### 9 Abstract

10 Middleware for ubiquitous and context-aware computing entails several challenges, including the need to balance between transpar-  
 11 ency and context-awareness and the requirement for a certain degree of autonomy. In this paper we outline most of these challenges, and  
 12 highlight techniques for successfully confronting them. Accordingly, we present the design and implementation of a middleware infra-  
 13 structure for ubiquitous computing services, which facilitates development of ubiquitous services, allowing the service developer to focus  
 14 on the service logic rather than the middleware implementation. In particular, this infrastructure provides mechanisms for controlling  
 15 sensors and actuators, dynamically registering and invoking resources and infrastructure elements, as well as modeling of composite con-  
 16 textual information. A core characteristic of this infrastructure is that it can exploit numerous perceptual components for context acqui-  
 17 sition. The introduced middleware architecture has been implemented as a distributed multi-agent system. The various agents have been  
 18 augmented with fault tolerance capabilities. This middleware infrastructure has been exploited in implementing a non-obtrusive ubiqui-  
 19 tous computing service. The latter service resembles an intelligent non-intrusive human assistant for conferences, meetings and presen-  
 20 tations and is illustrated as a manifestation of the benefits of the introduced infrastructure.

### 24 1. Introduction

25 Middleware deals with the coordination, cooperation  
 26 and interoperability of distributed components through  
 27 bridging the gap between applications and their underlying  
 28 low-level software and hardware infrastructure. Moreover,  
 29 it facilitates integration of components in distributed hetero-  
 30 geneous environments. Middleware systems and architec-  
 31 tures are becoming increasingly important as networks,  
 32 services and applications become more complex. These  
 33 architectures provide a basis for tackling stringent require-  
 34 ments regarding faster development and cost-effective oper-

ation. The latter requirements expand the scope of 35  
 middleware to address not only faster development, 36  
 deployment and integration, but also cost-effective systems 37  
 operation and management. To this end, emphasis is put 38  
 on designing, developing and deploying active systems, 39  
 which feature autonomic existence and are commonly clas- 40  
 sified as autonomic. Autonomic computing systems possess 41  
 several characteristics including that they are self-defining, 42  
 self-configuring, self-optimizing, self-healing, context- 43  
 aware and anticipatory. Middleware services and architec- 44  
 tures are gradually evolving to support autonomic comput- 45  
 ing systems [1]. 46

Several research issues come into foreground, when it 47  
 comes to supporting the visionary, yet constantly evolving 48  
 ubiquitous computing paradigm [2]. Ubiquitous computing 49  
 services aim at exploiting the full range of sensors and net- 50  
 works available to transparently providing services, regard- 51

 kos), [James.Crowley@inrialpes.fr](mailto:James.Crowley@inrialpes.fr) (J.L. Crowley).

less of time and end user's location [3,4]. A core characteristic of pervasive and ubiquitous computing systems is that they are context-aware, in the sense that they are able to provide services not only based on information that end users provide, but also based on implicit contextual information [5]. Implicit information is usually derived based on a rich collection of casually accessible, often invisible sensors that are connected to a network structure. Apart from context-awareness, ubiquitous computing systems feature increased dynamism and heterogeneity, which differentiate them radically from traditional distributed systems. The underlying ubiquitous computing infrastructures are more sophisticated and bring into foreground issues such as user mobility, disconnection, dynamic introduction and removal of devices, diverse network connections, as well as the need to blend the physical environment with the computing infrastructure [6]. Ubiquitous computing components are related to autonomic computing, since autonomy is a key to confronting these challenges. All major pervasive and ubiquitous computing projects (e.g. [7–11]) have built sophisticated middleware infrastructures. These projects reveal that middleware for ubiquitous computing is much more complex comparing to conventional distributed systems. However, they are focused on a specific set of middleware services facilitating their target applications. For example, some emphasize on context-awareness, others on transparent communications and mobility, while some others concentrate on autonomy. In this paper we describe a middleware infrastructure addressing a wide range of issues entailed in ubiquitous computing services. Specifically, this infrastructure provides mechanisms for service access, context modeling, control of sensors and actuators, directory services for infrastructure elements and services, as well as fault tolerance. We describe this infrastructure with particular emphasis on a framework for controlling sensors and actuators, as well as our approach for modeling situation states. Also, we describe the implementation of this framework over an agent platform. Overall this middleware infrastructure allows ubiquitous service developers to focus on the service logic of the implementation, rather than implementing the middleware. The various frameworks provide functionality that can be reused across different ubiquitous computing services.

Based on the introduced middleware platform, we have built a prototype ubiquitous computing service, namely the Memory Jog (MJ), which resembles a smart non-intrusive assistant for meetings and conferences. This service is built in the scope of a smart room, which comprises a rich sensing infrastructure comprising multiple sensors. A number of perceptual components such as for face detection and recognition, acoustic localization, person tracking and speech activity detection were implemented over this sensing infrastructure. These perceptual components were accordingly used to support context-awareness based on the introduced context modeling approach. In particular, perceptual components outputs were combined with a view

to identifying composite contextual states. Note that perceptual components were wrapped as agents and accordingly integrated to the rest agent based middleware framework.

The service logic of the Memory Jog made use of the introduced sensor and actuator control framework with a view to dynamically discovering hardware and software elements, and invoking their services. This framework facilitated the implementation of the Memory Jog service logic given that important middleware services were reused. Indeed, by reusing middleware services the Memory Jog service developers allocated effort on implementing the service logic, paying special attention in usability aspects, such as the intuitiveness of the user interface and the non-obtrusive nature of the service. These aspects were positively evaluated in the scope of simulation studies with end users. Main conclusion and results from these studies are also included in this paper.

The rest of the paper is structured as follows: Section 2 provides a taxonomy of middleware components for ubiquitous computing. Section 3, introduces our overall middleware architecture for ubiquitous computing services and positions it with respect to other prominent middleware frameworks for ubiquitous computing. Special emphasis is paid into describing our approach for context modeling, as well as a framework for dynamically controlling sensors, actuators and services. It is also illustrated that this middleware infrastructure was implemented as a distributed multi agent system. Section 4 describes presents the implementation of the Memory Jog service based on the introduced infrastructure. It also reports main results from simulation studies involving users. Finally, Section 5 summarizes the paper and outlines the main conclusions.

## 2. Taxonomy of middleware components for pervasive computing

Middleware architectures for traditional computing services aim at providing complete transparency of the underlying technology and their surrounding environment. While this provides several benefits it is not the ultimate goal in ubiquitous computing environments. These environments target context-awareness, which demands availability of knowledge and information about the surrounding environment. At the same time there is also a need for an appropriate degree of transparency, since this can reduce software complexity and optimize the use of system resources. As a result, ubiquitous computing middleware strives to achieve an optimal balance between awareness and transparency [2].

Other objectives of middleware architectures and components are to ease application developers in exploiting their capabilities. Efficient middleware architectures facilitate structured integration of components based on well-defined development processes and programming environments. Note however, that the efficiency of middleware components is audited based on the quality of their run-

164 time services. As a result, middleware enables the coopera-  
 165 tion between development support and runtime services.  
 166 This cooperation is particularly difficult in the scope of per-  
 167 vasive computing, given that middleware components  
 168 expose multiple interfaces to different application level  
 169 components, while also providing a multi-facet runtime  
 170 support. In particular, components supporting ubiquitous  
 171 computing can be classified according to their functional-  
 172 ity, as illustrated in the following paragraphs.

### 173 2.1. Transparent ad hoc communication

174 Middleware components in ubiquitous computing pro-  
 175 vide transparent communication between the diverse sens-  
 176 ors and devices engaged in the computing infrastructure  
 177 (e.g., cameras, microphone, computers, PDAs, smart  
 178 phones). Middleware components abstract the details of  
 179 communication channels and protocols and achieve inter-  
 180 operability regardless of the underlying network infrastruc-  
 181 ture. As devices are added and/or removed from the  
 182 network, systems and applications are notified. Publish-  
 183 subscribe mechanisms and popular XML messaging proto-  
 184 cols can be employed to this end.

### 185 2.2. Capture and transfer of sensor streams

186 Capturing sensor data is a prerequisite to obtaining  
 187 information about the surrounding environment. To this  
 188 end, low level middleware components interface with the  
 189 various sensors in order to obtain raw sensor data. Such  
 190 components include a rich set of capture drivers for differ-  
 191 ent sensors.

192 In the scope of ubiquitous computing applications, raw  
 193 sensor data is processed towards extracting context cues. In  
 194 most cases this processing is performed at different comput-  
 195 ing platforms that the host capturing data (Fig. 1). This  
 196 is mainly due to the need to exploit distributed computa-  
 197 tional power given that sensor processing might be compu-  
 198 tationally demanding. Therefore, there is a need for

199 additional components undertaking the graceful transfer  
 200 of sensor streams across the network for distributed pro-  
 201 cessing. Representative components falling in this category  
 202 are high performance sockets ensuring quality of service in  
 203 the delivery of sensor data. A prominent example of such a  
 204 middleware infrastructure is the NIST Smart Flow System  
 205 [12,13].

### 206 2.3. Raw signals processing

207 Raw sensor data is processed and contextual informa-  
 208 tion relating to location, identity and activity is obtained.  
 209 Such information constitutes a form of *elementary* context,  
 210 but it is important since it can serve as an anchor to deriv-  
 211 ing additional information [3]. Collecting elementary con-  
 212 text hinges on middleware components performing  
 213 computationally complex signal processing on the sensor  
 214 data (e.g., audio, visual streams). Such middleware compo-  
 215 nents include a wide range of perceptual technologies (e.g.,  
 216 person and object identification, people and object track-  
 217 ing, multimodal interactions, speech recognition, body  
 218 tracking).

### 219 2.4. Context acquisition – situation recognition

220 Context-awareness in ubiquitous computing is not limit-  
 221 ed to identifying people, objects and their locations. On the  
 222 contrary, the emphasis is on identifying situations compos-  
 223 ed of multiple forms of elementary context. As a result,  
 224 middleware components for modelling and dynamically  
 225 detecting situations are important to any non-trivial ubiq-  
 226 uitous computing service. Conventional programming lan-  
 227 guages provide limited or no support for context-  
 228 awareness. Furthermore, technologies providing support  
 229 for context-awareness are likely to present differences  
 230 across different programming languages. This creates por-  
 231 tability problems for context-sensitive applications, which  
 232 middleware architectures attempt to solve. Thus, middle-  
 233 ware must provide a uniform and common way to express

Fig. 1. Capture, transfer and distributed processing of sensor streams.

234 the software's context-awareness with minimal dependen-  
 235 cies on specific languages, operating systems, sensors or  
 236 environment.

### 237 2.5. Decision making – context triggered service logic

238 Context acquisition and situation recognition constitute  
 239 prerequisite steps in implementing the service logic. Service  
 240 logic in traditional applications is triggered on-demand  
 241 paradigm, i.e., upon users' requests. This paradigm is  
 242 essentially augmented in the scope of ubiquitous comput-  
 243 ing applications, since the service logic can also be triggered  
 244 automatically, based on the current context. Automatic  
 245 triggering may involve adapting to the new environment,  
 246 notifying the user, as well as communicating with other  
 247 computers or devices to exchange information. Context-  
 248 triggered service logic is a foundation for non-intrusive  
 249 services.

## 250 3. Middleware infrastructure for ubiquitous computing

### 251 3.1. Related work

252 This section presents key elements of a middleware  
 253 infrastructure devised and developed in the Computers in  
 254 the Human Interaction Loop (CHIL) project [14], with a  
 255 view to easing service development and application integra-  
 256 tion. CHIL emphasizes on the development of ubiquitous,  
 257 context-aware services in in-door environments, which are  
 258 equipped with numerous sensors (i.e., microphones and  
 259 cameras). These environments are conveniently called  
 260 'smart rooms'. Fig. 2 depicts the floor plan of one of the

four smart rooms that have been setup in the CHIL pro-  
 261 ject, namely the Athens Information Technology smart  
 262 room. Services developed in these smart rooms comprise  
 263 a large number of perceptual middleware components  
 264 (such as recognition and localization algorithms), which  
 265 provide contextual information on people and objects'  
 266 identity and location. Specifically, CHIL service developers  
 267 exploit a wide range of perceptive interface components  
 268 including a rich collection of 2D-visual components (i.e.,  
 269 person localization and tracking, body detection, head ori-  
 270 entation, face detection and recognition), 3D-visual percep-  
 271 tual components (i.e., person tracking, gesture/posture  
 272 recognition, head & hand tracking using stereo cameras,  
 273 pointing gesture recognition using stereo cameras), acous-  
 274 tic components (i.e., speech recognition (including far-  
 275 field), source localization, speech detection, speaker identi-  
 276 fication, acoustic emotion recognition, acoustic event clas-  
 277 sification, beamforming), as well as audio-visual  
 278 components (i.e., A/V person tracking, person identity  
 279 tracking, activity recognition, AVSR – mouth (lips) obser-  
 280 vation, emotion recognition). The middleware infrastruc-  
 281 ture presented in this section facilitates integration of  
 282 these components, as well as the fusion of their contextual  
 283 information with a view to deriving more sophisticated  
 284 context. The diversity of these technology components,  
 285 the potential sophistication and integration complexity of  
 286 the services, as well as the number of collaborating organi-  
 287 zations and demonstration sites, pose unique integration  
 288 challenges.  
 289

290 All non-trivial ubiquitous and pervasive computing pro-  
 291 jects have devised similar middleware infrastructures. The  
 292 Interactive Workspaces project at Stanford University [7]  
 293 focused on human interaction with devices and large  
 294 high-resolution displays. A key challenge in this project is  
 295 the coordination of multi-modal, multiuser and multi-de-  
 296 vice applications in different contexts. To this end the pro-  
 297 ject has developed the Interactive Room Operating System  
 298 (iROS) [15], which provides a reusable, robust and extensi-  
 299 ble software infrastructure enabling the deployment of  
 300 component based ubiquitous computing environments.  
 301 IROS supports various modalities and human-computer  
 302 interfaces, by tying together devices each one having its  
 303 own operating system.

304 The Oxygen project at MIT concentrates on a pool of  
 305 user and system technologies enabling pervasive human-  
 306 centered computing. In Oxygen applications special  
 307 emphasis is paid on automated, personalized access to  
 308 information, adapting the applications to users' preferences  
 309 and needs. In terms of middleware architecture, the Oxy-  
 310 gen project has produced the MetaGlue system [10], which  
 311 constitutes a highly robust agent platform, where agents  
 312 represent both local resources and interactions with those  
 313 resources. Metagluie relies on a custom distributed commu-  
 314 nication infrastructure enabling agents to run autonomously  
 315 from individual applications so they are always available  
 316 to service multiple applications. Metagluie is efficient in  
 317 implementing autonomous agents that significantly aug-

Fig. 2. Floor plan and sensors of the Athens Information Technology Smart Room.

318 ment the functionality of the space and facilitate user inter-  
 319 action. However, it provides no essential support for imple-  
 320 menting context-awareness. The latter is addressed in the  
 321 GOALS architecture [9], which is the evolution of the  
 322 MetaGlue system.

323 The EasyLiving system developed at Microsoft research  
 324 is another prototype ubiquitous computing architecture  
 325 [16]. Easy Living focuses both on the coordination of the  
 326 devices, but also on exploitation of contextual information.  
 327 Specifically, the system employs computer vision technolo-  
 328 gies for person-tracking and visual user interaction and  
 329 supports context-awareness based on a geometric model  
 330 of the world. It uses device-independent communication  
 331 and accordingly adapts the user interface.

332 The Aura system [8] targets pervasive computing envi-  
 333 ronments involving wireless communication, wearable or  
 334 handheld computers, and smart spaces. Aura provides soft-  
 335 ware architectural models that monitor an application and  
 336 guide dynamic changes to it. Thus, it provides opportuni-  
 337 ties for adapting to varying resources, user mobility, chang-  
 338 ing user needs and system faults.

339 The fact that each of the above projects has built its own  
 340 infrastructure manifests that there is no global unified  
 341 framework addressing all needs. Architectures tend to con-  
 342 centrate on particular application aspects. Some focus on  
 343 the co-ordination of physical space and devices (e.g., inter-  
 344 active workspaces), others on synchronizing multiple  
 345 modalities (e.g., Oxygen), and others on user mobility  
 346 and attention (e.g., AURA). Nevertheless, there is no  
 347 architecture providing the necessary level of sophistication  
 348 for supporting integration of a large number of autonomic  
 349 perceptual components, which is a major research chal-  
 350 lenge in CHIL.

### 351 3.2. Agent platforms

352 In order to alleviate the complexity of building middle-  
 353 ware for ubiquitous computing, we have strived as much as

354 possible to exploit pre-existing platforms and components.  
 355 In particular, we have taken advantage of middleware  
 356 developments supporting high performance transfer and  
 357 processing of streams, context-awareness and situation  
 358 detection, transparent ad hoc communication, as well as  
 359 autonomic features. These components have, however,  
 360 been appropriately customized towards implementing a  
 361 dynamic self-resilient infrastructure for provision of serv-  
 362 ices, along with a powerful mechanism for sophisticated con-  
 363 text modeling.

364 At the heart of our middleware infrastructure implemen-  
 365 tation is a distributed agent infrastructure. Agent infra-  
 366 structures facilitate the implementation of communication  
 367 between distributed entities based on rich semantics (see,  
 368 for example [17,18]). Moreover, they ease the implementa-  
 369 tion of transparent ad hoc communication between distrib-  
 370 uted components. Furthermore, agents provide a certain  
 371 degree of autonomy (e.g. [19]), which constitutes a sound  
 372 basis for implementing autonomic features.

373 Software agents lack the capabilities required to sup-  
 374 port high performance transfer of sensor streams. Infra-  
 375 structures for distributed transfer of sensor streams are  
 376 usually built as system level components that do not fea-  
 377 ture the high level capabilities of software agents. There  
 378 is therefore a need for integrating low level stream trans-  
 379 fer middleware with agent capabilities. A prominent way  
 380 to achieve this is to wrap low level middleware compo-  
 381 nents with agent based middleware, so that they behave  
 382 as software agents. The concept is depicted in Fig. 3,  
 383 which shows that low level components become part of  
 384 the agent infrastructure, as soon as an agent wrapper is  
 385 implemented on top of them. As all middleware compo-  
 386 nents expose agent behavior, they can be managed based  
 387 on a single higher layer interface. Note that in Fig. 3,  
 388 middleware components can be distinguished into two  
 389 basic sets according to their socket communication capa-  
 390 bilities. Higher performance sockets are required for the  
 391 distributed transfer of sensor streams, while agents com-

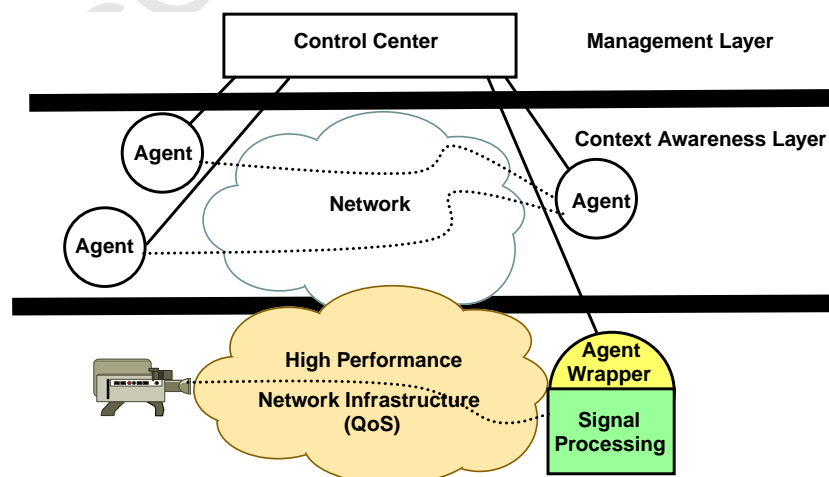

Fig. 3. Combining sensor processing and context-awareness.

392 municate through conventional socket interfaces. This is  
 393 illustrated in the figure in the form of two logically dis-  
 394 tinct network infrastructures, which, however, correspond  
 395 to the same physical network connectivity.

### 396 3.3. Middleware system overview

397 Fig. 4 depicts an anatomy of a multi-agent framework  
 398 supporting the implementation of ubiquitous and perva-  
 399 sive computing services. Specifically, this framework pro-  
 400 vides a set of functionalities that along with the sensing  
 401 infrastructure can be re-used across different ubiquitous  
 402 computing services. These functionalities include mecha-  
 403 nisms to:

- 404 • Control the sensors and actuators of the ‘smart room’.
- 405 • Control user access to services.
- 406 • Modeling composite contextual states based on combi-  
 407 nations of perceptual components.

409 Several ubiquitous computing services can leverage this  
 410 reusable functionality, which allows the service developer  
 411 to concentrate on implementing the service logic rather  
 412 than the middleware. Apart from this set of reusable com-  
 413 ponents and services, the framework implements ‘pluggable’  
 414 mechanisms for incorporating additional perceptual  
 415 components and sensors.

416 The framework consists of the following agents types:

- 417 • *Core Agents:* Core agents are independent of the service  
 418 and smart room installation independent. They provide  
 419 the communication mechanism for the distributed enti-  
 420 ties of the system. Moreover, core agents undertake

the control of the sensing infrastructure, while also  
 allowing service providers to ‘plug’ service logic into  
 the framework. Core agents include the:

- Device Desktop Agent, which implements the user  
 interface required for accessing the ubiquitous ser-  
 vices. A ‘pluggable’ mechanism allows the user inter-  
 face to be customized to the particular ubiquitous  
 computing service.
- Device Agent, which enables different devices to  
 communicate with the framework.
- Personal Agent, which constitutes the proxy of the  
 end user in the agent world. The personal agent con-  
 veys user requests to the agent manager, which are  
 accordingly handled by appropriate agents. It main-  
 tains the user’s profile in order to personalize the ser-  
 vices to the end user.
- Agent Manager, which allows the system to be  
 dynamically augmented with additional Service  
 Agents. Thus, the Agent Manager allows additional  
 basic, as well as ubiquitous computing services to be  
 incorporated to the system.

- *Basic Services Agents:* These agents incorporate the  
 service logic of basic services, which are tightly cou-  
 pled with the installed infrastructure of each smart  
 room. Basic services include the ability to track com-  
 posite situations, as well as the control of sensors  
 and actuators. Tracking of composite situations is  
 performed through the Situation Watching Agent (-  
 SWA) (Fig. 4) based on the context modeling app-  
 roach discuss in following paragraphs. Also, control  
 of sensors and actuators is performed through the  
 Smart Room Agent in a way that is also elaborated  
 in subsequent paragraphs. Furthermore, a Knowledge

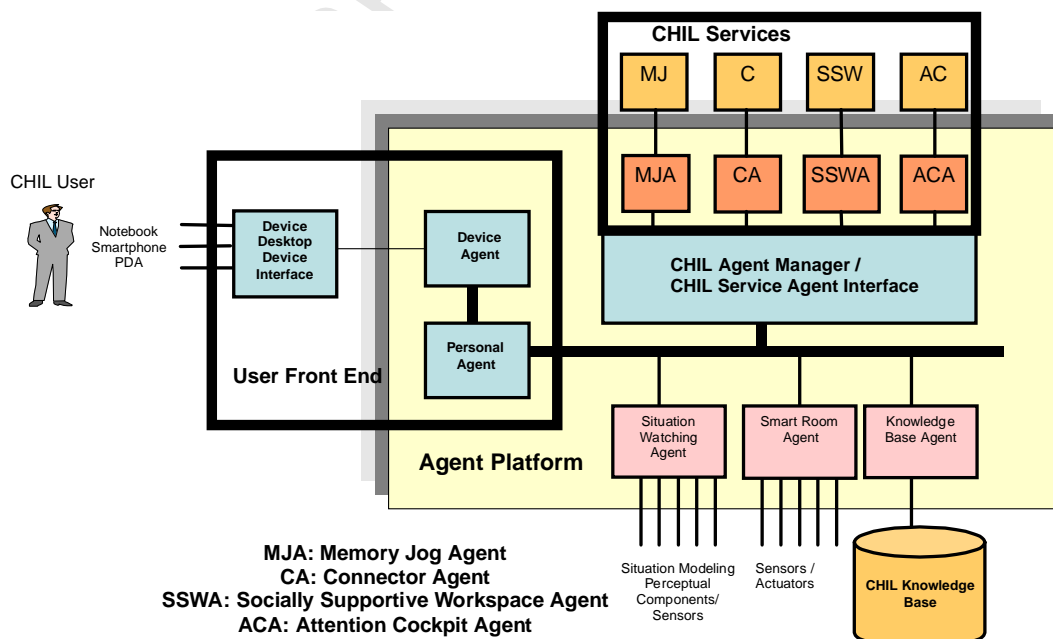

Fig. 4. Middleware infrastructure for ubiquitous computing.

454 Base Agent, allows the agents of the framework to  
455 dynamically access information on the state of the  
456 components of ubiquitous computing environment (-  
457 e.g., sensors, actuators, perceptual components), thr-  
458 ough a Knowledge Base Server that is supported as  
459 an ontology management system.

460 • *Ubiquitous Service Agents*: Ubiquitous service agents  
461 implement the non-obtrusive service logic of the vari-  
462 ous context-aware services. Each ubiquitous computing  
463 service is therefore implemented as a Ubiquitous ser-  
464 vice agent and accordingly plugged into the framework.  
465 In the scope of the CHIL project, several ubiquitous  
466 agents corresponding to various ubiquitous computing  
467 services are implemented and integrated into the fra-  
468 mework. A following section elaborates on the MJ se-  
469 rvice, which is implemented through the Memory Jog  
470 Agent (MJA). Fig. 4, depicts also the Connector Agent  
471 (CA), the Socially Supportive Workspaces Agent (SS-  
472 WA), and the Attention Cockpit Agent (ACA), which  
473 correspond to other CHIL services.  
474

475 This agent framework has been implemented based on  
476 the Java Agent Development Environment (JADE) plat-  
477 form [20]. In this implementation, agent communication  
478 is realized based on Foundation for Intelligent Physical  
479 Agents (FIPA) primitives [21]. Several aspects of this agent  
480 based middleware framework are described in [22]. More-  
481 over, information about the Knowledge Base and its use  
482 as a directory service for middleware components and ser-  
483 vices is provided in [23]. Following paragraphs describe the  
484 approaches adopted for context modelling and sensor/ac-  
485 tuator control, while also illustrating how agents have been  
486 augmented with autonomic capabilities.

#### 487 3.4. Context modeling

488 Context modeling middleware facilitates ubiquitous  
489 computing services with the ability to describe the state  
490 of their surrounding environment, while also providing  
491 mechanisms for accessing this description.

492 Accordingly, context modeling languages exploit this  
493 middleware to encode the detection of events that are nec-  
494 essary to initiate or terminate service actions. There are  
495 several approaches to modeling situations, which according  
496 serve as basis for implementing context-aware components.

497 The approach adopted and used along with the agent  
498 middleware infrastructure of the previous paragraph is  
499 based on the notion of networks of situation states [24].  
500 According to this approach a situation is considered as a  
501 state description of the environment expressed in terms of  
502 entities and their properties. A situation is a kind of state  
503 description composed of a conjunction of predicates. Pred-  
504 icates are truth functions that can take on logical or prob-  
505 abilistic values. Situations are defined in terms of an  
506 assignment of observed entities to ‘roles’, the properties  
507 of the entities assigned to roles, and the relations (i.e., re-  
508 lative properties) of the entities playing roles.

509 Entities have numerical attributes such as position, ori-  
510 entation, size, configuration or external appearance. These  
511 are tracked by perceptual components and can be used to  
512 compute relations. A relation is a predicate (truth) function  
513 computed over the attributes of one or more entities. Rela-  
514 tions may be represented by boolean or probabilistic truth-  
515 values. Each situation is defined in terms of a set of roles  
516 and relations. The concept of role is an important tool  
517 for simplifying the network of situations. It is common to  
518 discover a collection of situations for an output state that  
519 have the same configuration of relations, but where the  
520 identity of one or more entities is varied. A role serves as  
521 a ‘variable’ for the entities to which the relations are  
522 applied, thus allowing an equivalent set of situations to  
523 have the same representation. A role is played by an entity  
524 that can pass an acceptance test for the role, in which case,  
525 it is said that the entity can play or adopt the role for that  
526 situation.

527 A situation model describes activity using a network of  
528 situations. Such a model specifies the entities, properties  
529 and relations that must be observed towards triggering  
530 the service logic. Changes in individual or relative proper-  
531 ties of specified entities correspond to events that signal a  
532 change in situation. For example, in the scope of a meet-  
533 ing involving short presentations, at any instant, one per-  
534 son plays the ‘role’ of the ‘presenter’, while the other  
535 persons play the role of ‘attendees’. Dynamically assign-  
536 ing a person to the role of ‘presenter’ makes it possible  
537 to select perceptual component to acquire images and  
538 sound of the current speaker. Detecting a change in some  
539 role allows the system to reconfigure the video and audio  
540 acquisition systems.

541 Situation models determine the entities to observe, the  
542 properties to measure and the events to detect, and thus  
543 specify the selection and configuration of perceptual com-  
544 ponents (i.e., components realizing lower level signal pro-  
545 cessing). Accordingly, perceptual component outputs can  
546 be combined to identify situation states of the situation  
547 model, as shown in Fig. 5.

548 An example of a situation model targeting context-  
549 awareness for meeting activities involving an agenda and  
550 presentation is depicted in Fig. 6. This model signifies the  
551 importance of the following events with respect to a  
552 meeting:

- 553 • Commencement of the meeting.
- 554 • Start of the presentation on a particular agenda item  
555 (i.e., session of the meeting).
- 556 • Questions on each of the presentations.
- 557 • End of the presentation.
- 558 • End of the meeting.

559 Moreover, this model defines possible sequences of  
560 occurrence for these events, based on the arcs connecting  
561 the various situations. The context-aware middleware  
562 encoding this situation model makes provisions for both  
563 recognizing situation and situation transitions, but also  
564

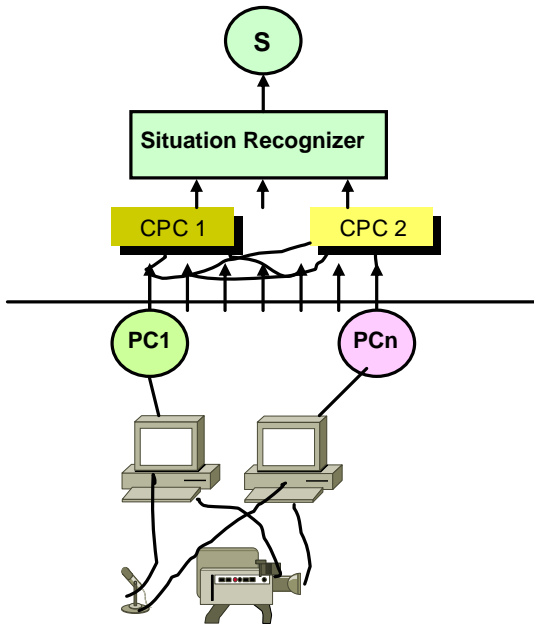

Fig. 5. Situation detection.

565 for triggering service logic associated with each of these  
566 situations.

567 Describing context as a network of situations may seem  
568 limiting and not scalable, mainly because it is unlikely to  
569 capture rich context based on a small set of situation states.  
570 Nevertheless, a situation model can be dynamically extend-

571 ed as new types of relations between entities are identified.  
572 Furthermore, there is always a possibility for making use of  
573 more than situation models in the scope of an application.  
574 Extending the situation model dynamically, while also  
575 dynamically switching between more than one model provides  
576 significantly more expressing power.

577 The network of situations approach has been imple-  
578 mented in the Situation Watching Agent of our framework.  
579 In particular, the Situation Watching Agent parses situa-  
580 tion models that are expressed in XML format. Each situa-  
581 tion model reveals the perceptual components and their  
582 configuration required to identify each state of the model.  
583 Once a situation model is loaded to the Situation Watch-  
584 ing Agent (based on an appropriate XML file), the Situation  
585 Watching Agent parses the model and identifies the percep-  
586 tual components required to track the states of the model.  
587 Accordingly, the SWA conveys requests for subscribing to  
588 these perceptual components to the Perceptual Components  
589 Wrapper Agent (PCWA). The PCWA queries the directory  
590 services (i.e., the knowledge base) to dynamically  
591 discover the properties and configuration of perceptual  
592 components, and then subscribes to them. The required  
593 perceptual components provide input to the PCWA, which  
594 acts also as a manager of these subscriptions. As the per-  
595 ceptual components send their output to the PCWA, the  
596 latter filters these outputs according to the properties of  
597 the subscription and forwards them to the SWA. The  
598 whole process is illustrated in Fig. 7. Thus, the Situation

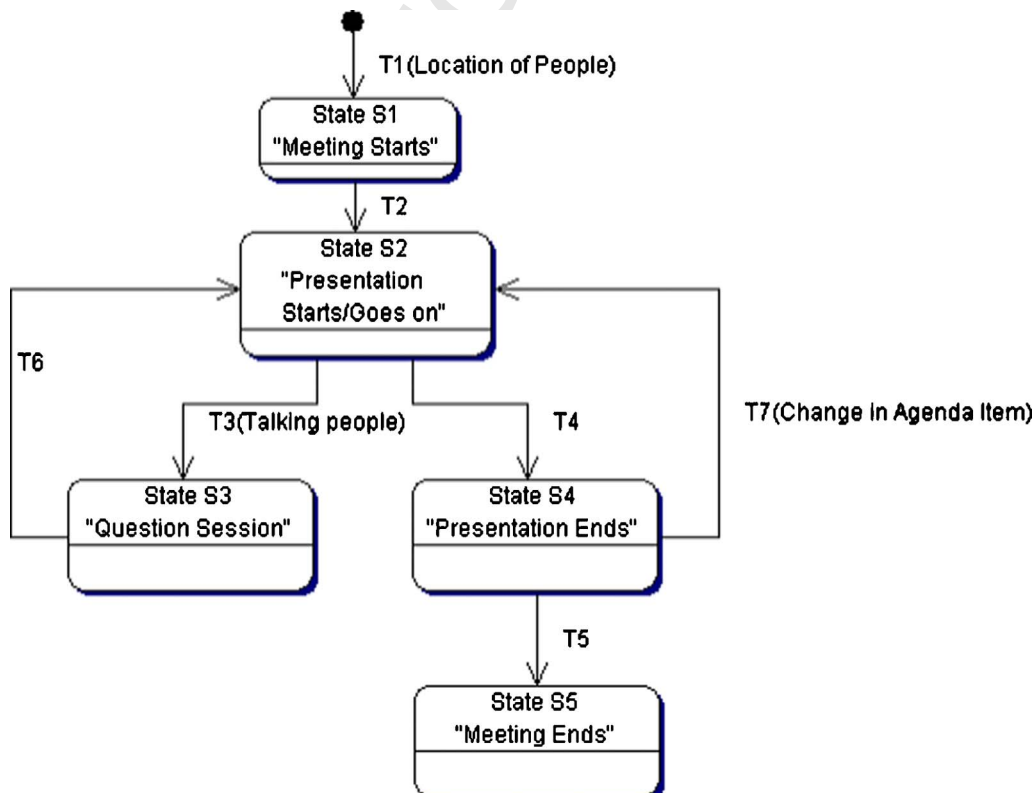

Fig. 6. A sample situation model.

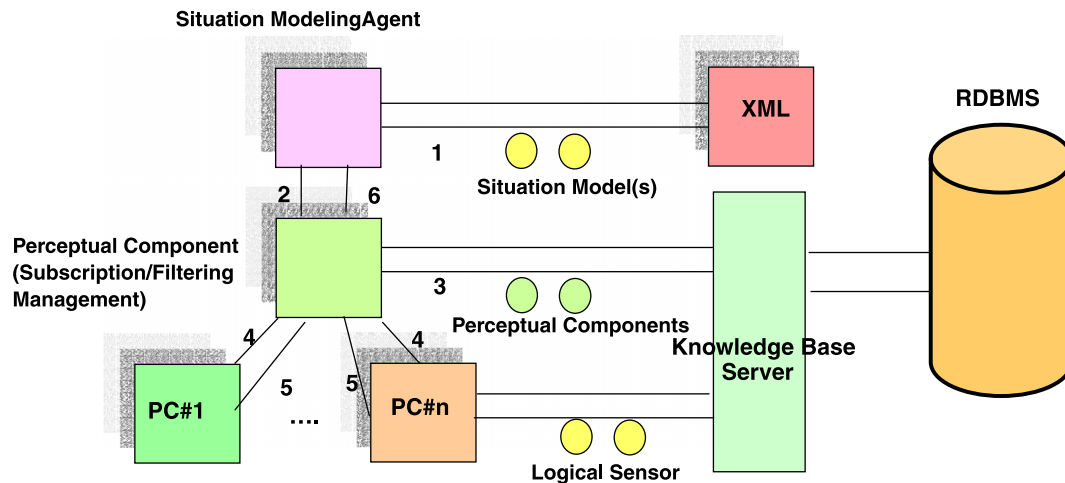

Fig. 7. Combining perceptual components to identify situation model states.

599 Watching Agent acts as a context broker, which is a quite  
600 common approach in context-aware architectures for  
601 smart spaces.

### 602 3.5. Agent based service oriented infrastructure – sensor and 603 actuator control

604 The introduced middleware infrastructure provides a  
605 common interface (API) for accessing and controlling the  
606 various hardware elements (i.e., sensors and actuators).  
607 To this end, sensor and actuators register with the directory  
608 service provided by the Knowledge Base Service. Sensor  
609 and actuator meta-data, which are registered within the  
610 knowledge base server, include information about the vendor,  
611 the model, the status, interfaces, capabilities, as well as  
612 the network addresses of the device. From an implementation  
613 perspective, we have concentrated on registering the  
614 two main types of sensors that exist in our smart room  
615 (Fig. 2), namely microphones and cameras. Thus, we have  
616 implemented three distinct proxy agents for these devices:  
617 one generic, one for microphones and one for cameras.  
618 The main responsibilities of these proxies are to:

- 619 • Represent sensors and actuators in the world of agents  
620 and provide access to the rest of the framework.
- 621 • Interact with the directory service of the knowledge  
622 base.

624 For each new device (i.e., sensor or actuator) that is  
625 installed in the room, a new proxy agent is instantiated  
626 as a mean to controlling the device. This proxy agent  
627 constitutes an agent wrapping to the device control capabilities.  
628 Upon the initialization of the device, the proxy agent  
629 is responsible for registering it with the knowledge base.  
630 Accordingly, it updates the indicated operational state  
631 of the device in the registry (for example, when the device  
632 shuts down or restarts). Finally, it translates requests  
633 from other agents of the framework, to device-specific  
634 calls.

635 Similarly to the infrastructure elements the framework  
636 controls various infrastructure specific (auxiliary) services.  
637 Developers of ubiquitous computing applications use the  
638 framework to dynamically access information on the  
639 available value-adding services installed in the infrastruc-  
640 ture. Prominent examples of such services include a  
641 text-to-speech (TTS) service, a display, and a targeted  
642 audio service. Information about these services is regis-  
643 tered using a proxy agent, similar to the case of sensor  
644 and infrastructure elements registration. The mechanism  
645 is illustrated in Fig. 8. A wrapper agent represents the ser-  
646 vices available to the agent platform, enables communica-  
647 tion with the rest of the framework, translates requests  
648 from the various clients to service-specific calls and inter-  
649 acts with the knowledge base. This wrapper agent pro-  
650 vides another level of abstraction. Specifically, all  
651 services that provide the same functionality (e.g., all  
652 TTS services) are wrapped by a service proxy of the same  
653 type (e.g., a TTS proxy). This service specific proxy han-  
654 dles all requests for that service, being also responsible to  
655 forward them to specific implementations and machines  
656 that host this service. The service proxy retrieves also  
657 dynamically information (from the knowledge base) about  
658 the existence, the properties and the operational status of  
659 the available services. In the case where there is no avail-  
660 able provider of this service and the proxy declares inca-  
661 pable of fulfilling the request.

662 Note that the particular algorithm for selecting a service  
663 implementation depends on the targets and goals of the  
664 overall ubiquitous computing service. For example, a  
665 TTS service instance, as well as a display service instance  
666 may be selecting by the corresponding proxies based on a  
667 variety of criteria involving people locations an orientation  
668 within the smart room.

669 Fig. 8 illustrates the implemented registration mecha-  
670 nism enabling discovery and manipulation of services and  
671 infrastructure elements. The mechanism involves the fol-  
672 lowing steps:

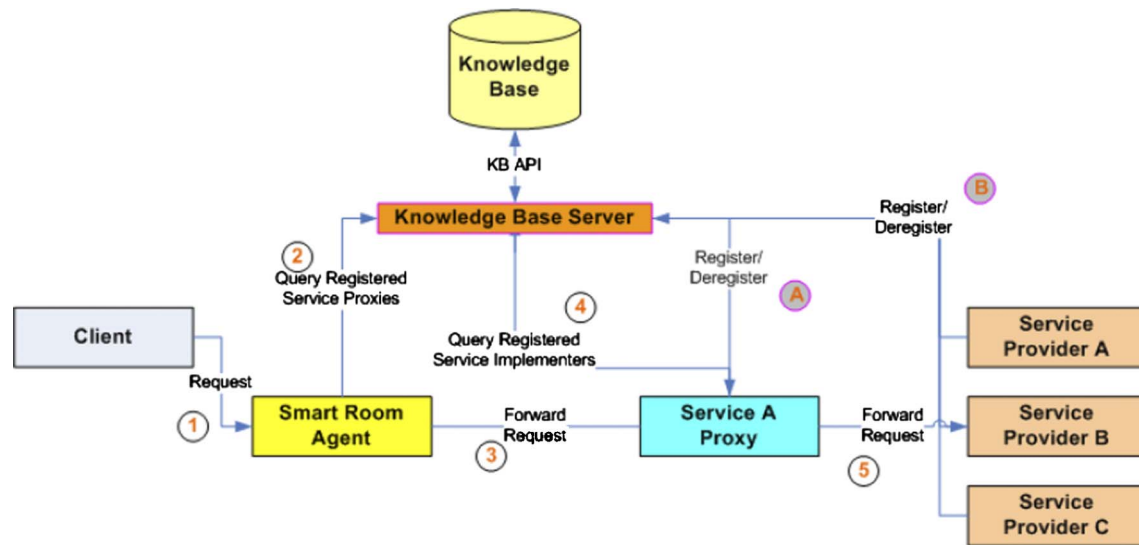

Fig. 8. Registration, dynamic discovery and invocation for the services of the system.

- The proxy of a specific service registers into the system (step A).
- All the providers of this specific service also register themselves into the system (step B).
- When clients want request a particular service invocation, they send a request to the gateway for all the services (step 1), which is a dedicated agent and is called the Smart Room Agent (SRA).
- The SRA searches the registry in order to see if there is a proxy for such a service (step 2).
- Assuming that a proxy is found it forwards the request to it (step 3).
- When the service proxy receives a new request, it checks the registry to find available service providers (step 4).
- A selection algorithm is used to decide to which service provider to forward the request. Following the selection the request finally is received and served by a service provider (step 5).

Note that the all information is dynamically looked up at the knowledge base. This is performed to support for service providers dynamically coming into and going out of the system.

### 3.6. Autonomic features

Agent platforms support certain autonomic features of a distributed system, including the abilities to persist, clone and move (migrate) components to other hosts. However, there is also a need to implement application specific functionality for discovering agent deficiencies, since the later are differently defined in the scope of an application.

Based on the JADE platform we augmented all agents of the framework with the capability of querying agent

components about their status. Thus, we implemented a ‘ping’-like functionality for all agents of the framework. Moreover, as agents discover the status of other agent entities, we have implemented functionality enabling agents to adapt their behavior to the status of other agents. This is particularly important in the case where the availability of an agent entity is a prerequisite for the operation of others. Specifically, in the middleware framework presented in Fig. 4, several agents depend on others. For instance, the Situation Watching Agent relies on underlying wrappers of perceptual components to support situation recognition. In general, an agent has a set of dependencies expressed as a dynamic list of other agents. As a first step to ensuring autonomy and maximum service availability of the system, we implemented functionality allowing every agent to keep track of the list of its dependants and accordingly adapt its functionality. Adaptation results in downgrading or upgrading the functionality and features offered by the particular agent, depending on the availability of other agents.

As a second step to autonomy we provided middleware for self-healing functionality. This was achieved through migrating dependant agents to a different execution environment (e.g., machine or agent container) upon detection of problems with their availability. To this end the migration process is combined with the detection (‘ping’) functionality outlined above. Agent migration is undertaken from another entity that is able to detect the problem. The delegation of this entity is implemented based on either an Autonomic Manager agent entity, which undertakes the role of migrating and restarting agents. The autonomic manager exploits the ‘ping’ functionality to detect failing agents. Fig. 9 depicts the state diagram of an agent incorporating autonomic functionality. This agent ‘pings’ dependant agents and accordingly modifies its state.

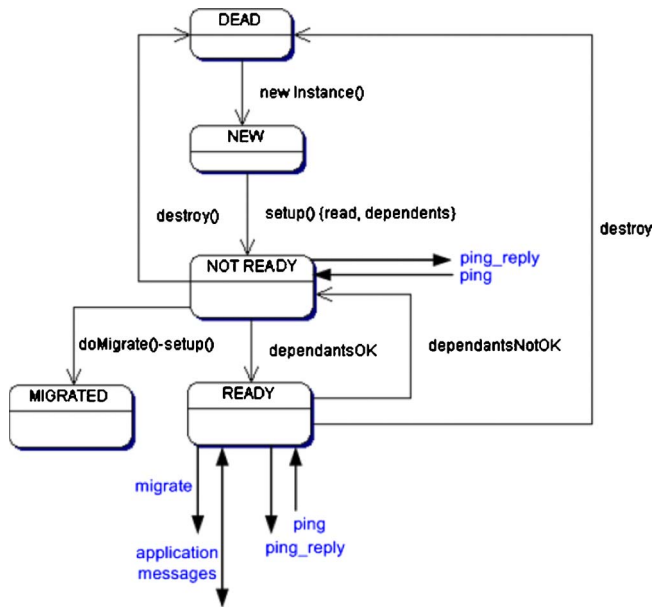

Fig. 9. Pinging dependent agents and agent migration.

## 743 4. Ubiquitous computing application implementation

### 744 4.1. Overview of the Memory Jog service

745 The middleware infrastructure outlined in the previ-  
 746 ous section served as a basis for implementing ubiqui-  
 747 tous computing services. In the sequel we present the  
 748 implementation of an application constituting a non-in-  
 749 trusive assistant for events such as lectures, meetings,  
 750 presentations occurring in in-door environments. The  
 751 primary function of this assistant is to track context  
 752 and provide pertinent information facilitating humans  
 753 to accomplish tasks during these events. Since provision  
 754 of pertinent information serves as a memory aid to  
 755 humans, we conveniently call this ubiquitous computing  
 756 service ‘Memory Jog’ (MJ). The MJ resembles a con-  
 757 text-aware conference assistance [25] and has been  
 758 selected for studying computing services based on  
 759 implicitly derived information in the scope of the CHIL  
 760 project.

### 761 4.2. Distributed multi-agent implementation of the Memory 762 Jog

763 The MJ service was implemented in the smart room  
 764 depicted in Fig. 2, which consists of:

- 765 • One 64 channel microphone array [26].
- 766 • Microphones for localization, in particular three clus-  
 767 ters, each consisting of four microphones.
- 768 • Four fixed cameras, used for overall monitoring of the  
 769 room.
- 770 • One active camera with pan, tilt and zoom (PTZ  
 771 camera).
- 772 • A panoramic (or fish-eye) surveillance camera.

The service implementation takes advantage of the mid-  
 775 dleware infrastructure depicted in Fig. 4. At the lowest  
 776 level of this infrastructure, perceptual components process  
 777 sensor streams. To this end, middleware capturing data  
 778 from all available sensors has been produced. Captured  
 779 data are made available for processing in any of the sys-  
 780 tems, based on the distributed NIST Smartflow middle-  
 781 ware (NSFS). Hence, the NSFS system constitutes the  
 782 solution adopted for high performance transport of  
 783 streams.  
 784

Perceptual processing of sensor data is based on the fol-  
 785 lowing components technologies that have been developed  
 786 in our lab:  
 787

- Acoustic identification and localization of the speaker  
 788 [27].
- Face Detection, Recognition and People tracking  
 789 [28,22].
- Detection of speech activity.  
 790

Perceptual processing is computationally demanding.  
 794 Therefore, perceptual components are implemented in  
 795 low-level high performance languages (i.e., C/C++), and  
 796 wrapped as JADE agents in line with the notion illustrat-  
 797 ed in Fig. 3. Wrapping was implemented through a per-  
 798 ceptual components wrapper agent, as shown in Fig. 9.  
 799 Accordingly, we combined perceptual components in  
 800 order to create higher level perceptual components that  
 801 can track situations as illustrated in Fig. 5. Fig. 10 depicts  
 802 how elementary components tracking the agenda, identi-  
 803 fying speech activity, identifying faces and recognizing  
 804 people are used to form composite perceptual components  
 805 that keep track of the status of a whiteboard and the  
 806 meeting room table, with respect to the meeting partici-  
 807 pants. The higher level ‘Table Watcher’ and ‘White-board  
 808 Watcher’ perceptual components are accordingly use to  
 809 track situations.  
 810

The situations to be tracked are driven by the situation  
 811 model depicted in Fig. 6. This situation model is loaded in  
 812 the Situation Watching Agent based on an XML file  
 813 describing the model. This XML format specifies the per-  
 814 ceptual components output combinations leading to detect-  
 815 ing a particular situation. These combinations are also  
 816 described in Table 1, which specifies the perceptual compo-  
 817 nents values that determine the transition to each one of  
 818 the contextual states of the situation model.  
 819

The subscription mechanism illustrated in Fig. 7, was  
 820 exploited to detect situations and triggering the service log-  
 821 ic. The service logic of the MJ service was based on a wide  
 822 range of services offered within the smart room. Smart  
 823 room services were implemented based on the introduced  
 824 sensor, services and actuator control framework. Specifi-  
 825 cally, the following services were implemented based on  
 826 this framework: (a) a TTS (Text-to-Speech) service, (b) a  
 827 slide show/display service and (c) a storage service allowing  
 828 access to a relational database. These services were invoked  
 829 by the service logic, either based on current context, or  
 830 upon end users’ requests. The latter requests can be issued  
 831

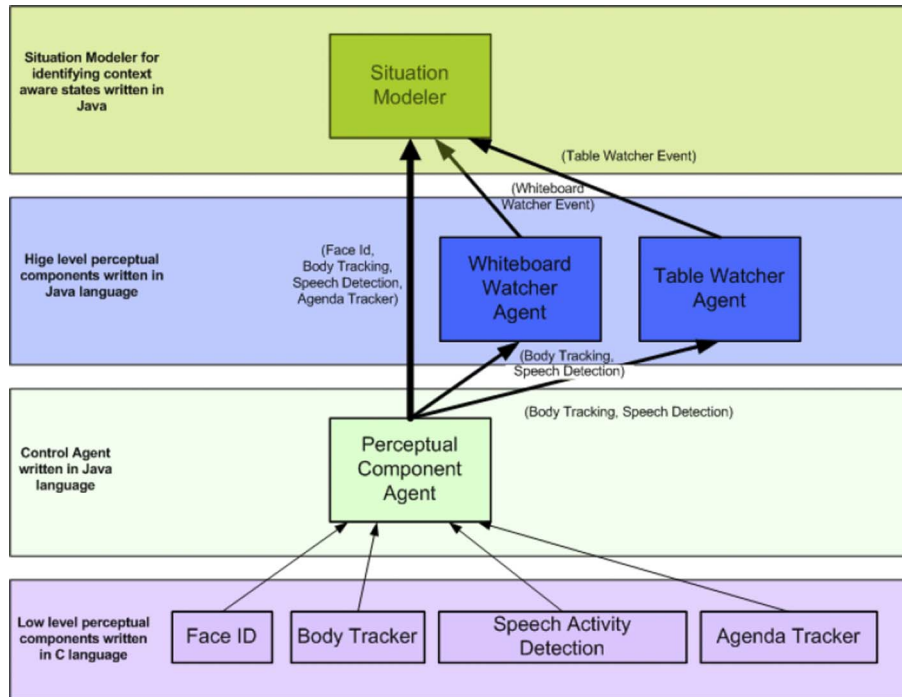

Fig. 10. Perceptual components supporting the situation model.

Table 1  
Identifying composite contextual states through combining perceptual components' outputs

Situation transition	Combinations of perceptual components outputs
NIL → S1	TableWatcher = $N$ ( $N$ people in table area) and Speech Activity (SAD = true)
S1 → S2	WhiteboardWatcher = 1 (1 person in speaker area), TableWatcher = $N - 1$ ( $N - 1$ people in table area)
S2 → S3	Acoustic Localization (Table Area)
S3 → S2	Acoustic Localization (Speaker Area)
S2 → S4	WhiteboardWatcher = 0 (no person in speaker area), TableWatcher = $N$ ( $N$ people in table area)
S4 → S5	TableWatcher = 0 (no people in table area)

832 by a graphical user interface that is used by the end user to  
 833 visualize MJ information, as well as to allow interaction  
 834 with the smart room. A snapshot of this interface is provided  
 835 in Fig. 11.

#### 836 4.3. Autonomic features

837 All these agent types extend the same agent class, which  
 838 realizes transparent communication capabilities, subscrip-  
 839 tions, polling, as well as agent discovery and communica-  
 840 tion. In order to ensure the autonomic functionality of  
 841 the overall system, we augmented our basic JADE agent  
 842 class with additional failure detection and healing function-  
 843 ality as outlined in the previous section.

844 Autonomic functionality was implemented as an addi-  
 845 tional layer over the basic JADE functionality (Fig. 12).  
 846 Therefore, all agent types described above we endowed  
 847 with healing capabilities since they were based on the  
 848 same augmented version of JADE agent. Therefore,  
 849 autonomy constitutes a vertical pillar of all distributed  
 850 entities.

#### 4.4. Users evaluation

851  
 852 The overall implementation of the MJ service confronted  
 853 a host of technical challenges as outlined above. Apart  
 854 from technical challenges however, ubiquitous services  
 855 need to take into account user issues, with a view to ensur-  
 856 ing that services are appealing to end users. User accep-  
 857 tance is a hot issue for non-obtrusive services, given that  
 858 the vast majority of end users are not acquainted with  
 859 the emerging context-aware computing paradigm.

860 In order to evaluate the MJ service prototype in terms of  
 861 user acceptance, we performed two simulations studies. In  
 862 each case one potential end-user ('the subject') was asked  
 863 to use the MJ service along with members of the design  
 864 team who played as actors in the scenario. The subject of  
 865 the study was well briefed on the CHIL project, the particu-  
 866 lar scenario and the background to the MJ service. Mem-  
 867 bers of the design team configured the scenarios and made  
 868 observations relating to the end user's behavior. Upon  
 869 completion of each simulated scenario the user was inter-  
 870 viewed to gain feedback about the service usability, the

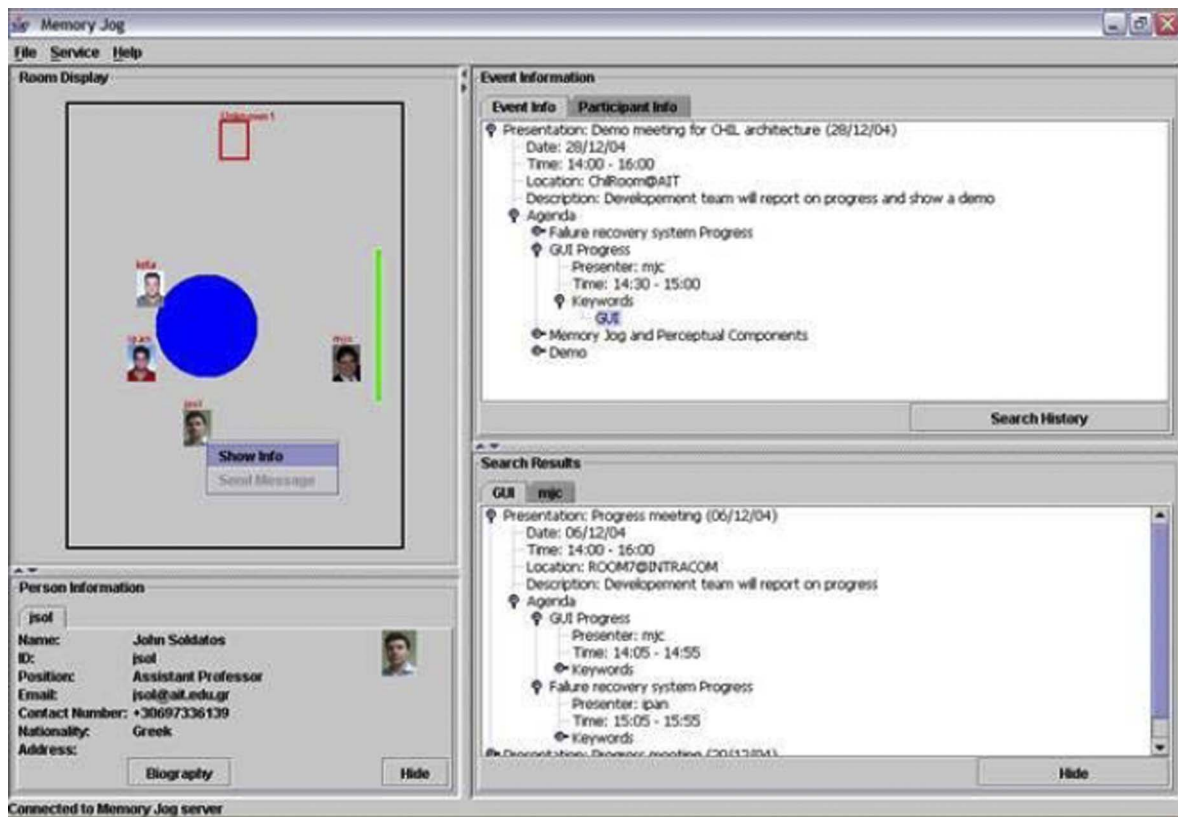

Fig. 11. A snapshot of the Memory Jog user interface.

Fig. 12. Enhancing software agents with autonomic functionality.

871 potential impact of the service, as well as to get ideas about  
872 possible improvements and additions to the service.

873 Both scenarios occurred in the room depicted in Fig. 2.  
874 The first scenario involved a simple presentation with two  
875 participants. The purpose of this scenario was to provide  
876 a fictional example according to which the initial service  
877 prototype was designed. As such the context is not neces-  
878 sarily one that would occur in the real world. It involves  
879 two developers in the room and one developer who is a vir-  
880 tual participant and is not physically present in the room.  
881 The presentations were about recent work that each of  
882 the participants has done.

883 The second scenario involved a meeting, where partici-  
884 pants aimed at reporting the progress of their work on a  
885 project. In particular, this involved a regular progress  
886 meeting of four developers and a project manager, in which  
887 each member of the team presents the latest developments  
888 in their work. A member of the administration of the insti-  
889 tution also attends the meeting as new hardware and soft-  
890 ware needs to be purchased and they are responsible for

891 approving the purchase. The regular meeting is also used  
892 to address high-level project management a system design  
893 issues.

894 The simulation studies revealed several issues with  
895 respect to the service prototype. As far as the intuitiveness  
896 of the user interface is concerned, the interface was gener-  
897 ally perceived as being user friendly. Also, the information  
898 displayed was easily understood and accessed. However,  
899 users declared that certain features (e.g., the search button)  
900 need to be made more obvious.

901 With respect to the level of interaction and obtrusiveness  
902 of the MJ service, the current functionality was perceived  
903 not to be overly intrusive in that it did not require a great  
904 deal of user input to respond to and adapt to the progress  
905 of the event. Recommendations were made, however, to  
906 make changes more obvious when they occur. A suggested  
907 way to achieve this was the use of interactive timed pop-up  
908 info boxes.

909 End users suggested also additional functionalities, such  
910 as the ability to view the presentation slides through the  
911 interface, and to possibly make personal annotations on  
912 the slides. Moreover, users asked for pop-up or audio  
913 reminders about the timing of the event, so that speakers  
914 are reminded of when their time is running out. More triv-  
915 ial recommendations concerned showing a reminder at the  
916 end of the event as to when the next event in a sequence is  
917 scheduled, as well as to who should attend. These sugges-  
918 tions will be seriously taken into account into designing  
919 the next version of the MJ service.

## 920 5. Conclusions

921 Middleware architectures boost rapid application devel-  
922 opment in the scope of complex and heterogeneous net-  
923 work and computing infrastructures. The increasingly  
924 important role of middleware components is intensified,  
925 when it comes to addressing ubiquitous computing applica-  
926 tions and services. Middleware infrastructures for such  
927 applications impose a need for balancing between transpar-  
928 ency and context-awareness, while at the same time tack-  
929 ling with more sophisticated environments in terms of  
930 hardware and software. Furthermore, a ubiquitous com-  
931 puting application asks for a wide range of runtime services  
932 such as context-awareness, sensor streams capturing, trans-  
933 fer and processing, dynamic service discovery and invoca-  
934 tion, as well as autonomic capabilities.

935 In supporting these features, a host of middleware com-  
936 ponents have to be implemented and integrated. Agent  
937 platforms provide a sound foundation for implementing  
938 such runtime services in a distributed environment. In this  
939 paper we have introduced an agent based middleware  
940 framework, which can ease the implementation of sophis-  
941 ticated context-aware services in appropriately configured  
942 in-door environments (called ‘smart rooms’). Smart rooms  
943 comprise a rich set of video and acoustic sensors, enabling  
944 several perceptive interfaces to operate and provide ele-  
945 mentary context cues. The introduced agent framework  
946 provides functionality for service access control, personal-  
947 ization, context modeling, as well as of dynamic control and  
948 management of sensors and actuating devices. Context  
949 modeling relies on the network of situations approach,  
950 which allows composite contextual states to be detected  
951 and tracked based on a combination of perceptual compo-  
952 nents outputs. The sensor and actuator control framework,  
953 allows ubiquitous computing services to dynamically access  
954 information on the status of infrastructure elements, as  
955 well as to invoke their services. Moreover, the agent frame-  
956 work has been augmented with fault tolerance capabilities  
957 ensuring that failures are timely detected and restored.

958 Based on this agent framework, we have implemented  
959 the Memory Jog, an intelligent non-obtrusive service pro-  
960 viding pertinent information and assistance in the scope  
961 of meetings, seminars and presentations. This implementa-  
962 tion has leveraged the capabilities of the agent based frame-  
963 work, therefore allowing the service developer to focus on  
964 the service logic implementation rather than the middle-  
965 ware. In implementing this service we have taken advan-  
966 tage of a wide range of perceptive interfaces including  
967 face detection, face recognition, person tracking (both visu-  
968 al and acoustic), as well as speech activity detection. The  
969 corresponding perceptual components have been used to  
970 trigger a simple situation model, which has been encoded  
971 into the agent framework. Following situation detection,  
972 the Memory Jog leverages the sensor, service and actuator  
973 control framework to invoke TTS services, display services,  
974 as well as storage services allowing the retrieval of past  
975 information relating to the current contextual state.

## Acknowledgements

This work is part of the FP6 CHIL project (FP6-  
506909), partially funded by the European Commission un-  
der the Information Society Technology (IST) program.  
The authors acknowledge valuable help and contributions  
from all partners of the project, especially from partici-  
pants in Work-package 2 dealing with the architecture  
and software infrastructure supporting the CHIL services.  
Special thanks also to Michael Carras, Dr. Pnevmatikakis  
and Dr. Talantzis for their valuable contribution in setting  
up and configuring our smart room infrastructure.

John K. Soldatos, was born in Athens, Greece in 1973. He obtained his Dipl-Eng. degree in 1996 and his PhD in 2000, both from the Electrical and Computer Engineering Department of the National Technical University of Athens (NTUA). He has had an active role in several EU co-funded research projects (EXPERT AC-094, WATT AC-235, IMPACT AC-324, Chameleon EP 20597, CATCH-2004 IST-1999-11103, and LION IST-1999-11387), and is now involved in the CHIL-FP6-506909 project. He has also consulted in many ICT projects for leading Greek enterprises (INTRACOM S.A, PEGASUS S.A, IBM Hellas S.A, OTE S.A, TEM-AGON S.A). Dr. Soldatos has extensively lectured in NTUA and AIT, while he has also given numerous invited lectures. As a result of his activities he has co-authored more than 60 papers published in international journals and conference proceedings. Since March 2003 he is with Athens Information Technology, where he is currently an Assistant Professor. His current research interests are in Pervasive/Ubiquitous and Autonomic Computing, Grid Computing and Broadband/Traffic Control.

Ippokratis Pandis is a Ph.D. candidate at Carnegie Mellon University (CMU). Before joining CMU, Ippokratis was member of the Autonomic and Grid Computing research group of Athens Information Technology (AIT), where he worked for the CHIL-FP6-506909 project. Ippokratis has been interested and holds publications to several conferences in the areas of database systems, middleware for ubiquitous computing and hypertext/hypermedia systems. Ippokratis got his B.Sc. from the Computer Engineering and Informatics Department (CEID) of the University of Patras, Greece, and his M.Sc. from the Information Networking Institute (INI) of the Carnegie Mellon University.

Konstantinos Stamatis, obtained his Master of Engineering degree in 2002 from the National Technical University of Athens and his Master of Science degree in Athens Information Technology, after the completion of MSIN program of Carnegie Mellon University. Mr. Stamatis has knowledge of C, C++ and Java programming languages, experience in implementing software applications, as well as in Unified Modeling Language and Soft Systems Methodology. His current research interests lie in the fields of hardware design and ubiquitous/pervasive computing systems. He is currently involved in the CHIL-FP6-506909 project.

Lazaros C. Polymenakos, obtained his electrical engineering and computer science degree from the National Technical University of Athens Greece (1989), and his Masters (1991) and Doctoral degrees (1995) from the Massachusetts Institute of Technology, Cambridge, MA, USA. Since 1995 he has worked with the IBM Human Language Technologies group on robust methods for automatic speech recognition in the presence of external noise and in varying channels. He has worked on methods for improving accuracy in speech recognition in embedded devices, and is the author of several technical publications, presentations and patents. In 1996 he was visiting professor at Rutgers University, NJ, USA. In 1998, he joined IBM Hellas, SA where he has focused on research and development for the Greek speech recognition system. Since 2002, he has been a faculty member of AIT, where he focuses on research in signal processing, perceptual interfaces and distributed systems.

James L. Crowley, directs the GRAVIR laboratory (CNRS UMR 5527) at the INRIA Rhone-Alpes research center in Montbonnot (near Grenoble), France. He holds the post of Professor at the Institut National Polytechnique de Grenoble (INPG), where he teaches courses in Computer Vision, Signal Processing, Pattern Recognition and Artificial Intelligence at l’ENSIMAG (Ecole Nationale Supérieure d’Informatique et de Mathématiques Appliquées). Professor Crowley has edited two books, five special issues of journals, and authored over 180 articles on computer vision and mobile robotics. He ranks number 1466 in the CiteSeers most cited authors in Computer Science (July 2004).
